

# Principles for computing viability kernels and resilience values

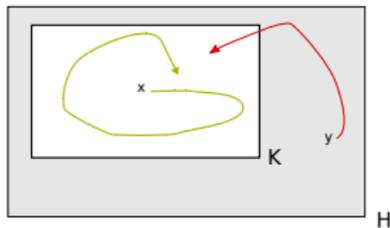

Laetitia Chapel

Patres tutorial workshop  
22 october 2009

- Control a dynamical system such that
  - **Viability perspective:** it survives inside a given set of admissible states
  - **Resilience perspective:** it maintains or restores its property of interest lost after disturbances
- State  $x(t)$ , controls  $u(t)$

$$\begin{cases} x'(t) = \varphi(x(t), u(t)), \text{ for all } t \geq 0 \\ u(t) \in U(x(t)) \subset \mathbb{R}^q \end{cases} \quad (1)$$

# Introduction

## Resilience in the viability theory framework

### Specific framework

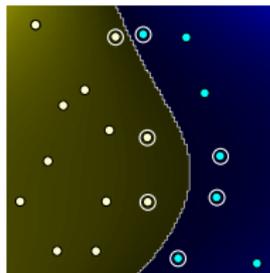

- Viability theory (Aubin)
- Tool: viability algorithm (Saint-Pierre)
- First step: viability kernel approximation
  - **But** the algorithm suffers the dimensionality curse, in the state and control space
- Second step: compute the resilience values
- Third step: control the system

Idea: sum up the set of points by a function

### Support vector machines (SVMs)

- Classification method
  - **Inputs:** training set,  $n$  points with labels  $+1 / -1$
  - **Outputs:** linear combination  $f(x) = \sum_{i=1}^n \alpha_i y_i k(x, x_i) + b$
- Particular solution
  - $\alpha_i$ : influence of a point on the solution  $\rightarrow$  parsimonious
  - $k(x, x_i)$  (virtually) maps the points on a feature space
  - non-linear solution in the input space

$$k(x, x_i) = \exp\left(-\frac{\|x-x_i\|^2}{\sigma}\right)$$

### Objectives

- Viability kernel and resilience values approximation algorithms
  - in a high (?) state space
  - in a high control space
- Compact and fast controllers

### View points

- Theoretical
- Practical

1. SVMs viability kernel approximation
2. Viability kernels active learning
3. Approximating capture basins with SVMs
4. Resilience computation
5. Conclusion - In practice

# SVMs viability kernel approximation

One simple example: population problem

- Simple example of a population growth in a limited space
- Dynamical system

$$\begin{cases} p(t + dt) = p(t) + p(t)y(t)dt \\ y(t + dt) = y(t) + u(t)dt \end{cases} \quad (2)$$

- Under constraints
  - $p \in [p_{min}, p_{max}]$
  - $y \in [y_{min}, y_{max}]$
  - $u \in [-u_{max}, u_{max}]$

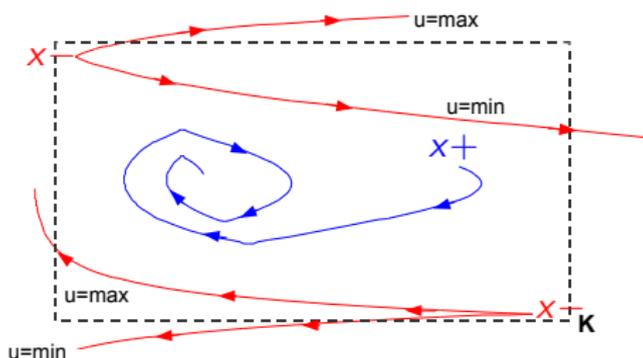

# SVMs viability kernel approximation

One simple example: population problem

How controlling a dynamical system such that it always remains in  $K$  ?

- Approximate the viability kernel of the system

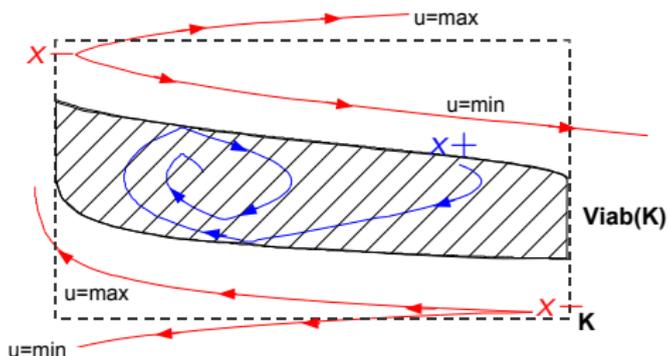

# SVMs viability kernel approximation

One simple example: population problem

How controlling a dynamical system such that it always remains in  $K$  ?

- Viability heavy controller

### Viability kernel approximation with a classification method

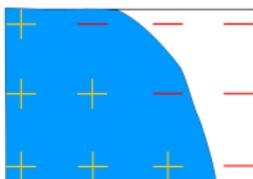

- Iterative algorithm, based on the Saint-Pierre algorithm
- Discretization de  $K$
- Learning set, contains the grid points with labels
  - +1 if the point is viable at the next iteration
  - -1 otherwise

# SVMs viability kernel approximation

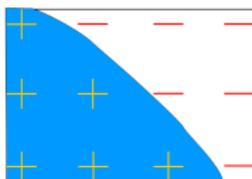

## Viability kernel approximation with a classification method

### Theorem

Under some conditions on the learning quality and on the dynamics, the algorithm gives an approximation that converges towards the actual kernel when the grid resolution tends to 0

OK

OK

non OK

# SVMs viability kernel approximation

## Viability kernel approximation with a classification method

### SVMs as a classification procedure: pros

- Allows one to use an optimization method (gradient descent) to find a viable control
- Allows one to work with several time steps at the same time
- The SVMs function can be defined as a controller
- The solution is parcimonious: less points in memory?

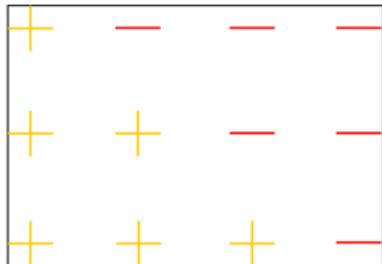

# SVMs viability kernel approximation

## Application example

### Progressive approximation of the viability kernel

- State space in 2 dimensions, 2601 points, 6 time steps

- 12 iterations, 19 SV

### SVMs viability heavy controller

- Same control  $u_0$  until the next state reaches  $f(x) < \Delta$
- Find a viable control, using a gradient descent on  $f$
- More or less cautious controller, anticipating on several time steps

Controller example (5 steps anticipation)

### Conclusion [Viability kernel approximation]

- Use of SVMs to approximate a viability kernel
  - defines **compact controllers**
  - **allows** one to deal with problems on high control space (thanks to the control optimization)
  - **doesn't allow** to deal with problems on high state space (discretization of the state space)

1. SVMs viability kernel approximation
2. Viability kernels active learning
3. Approximating capture basins with SVMs
4. Resilience computation
5. Conclusion - In practice

# Viability kernels active learning

## Definitions

- **active learning:** limits the number of points to label / the training set size
  - label points is costly
  - the grid size is exponential with the dimension
  - learning a SVM function is quadratic with the training set size
- We use the parsimonious property of the SVMs

# Viability kernels active learning

## Active learning algorithm

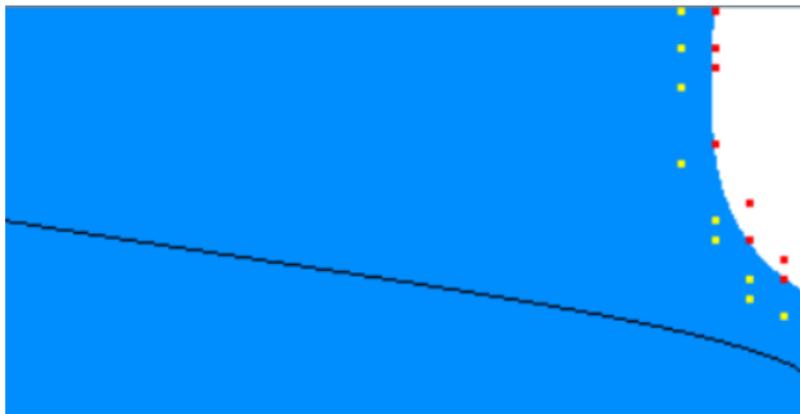

- 
- **Aim:** use a number of points close to the number of SVs
  - We progressively add the points the more likely to be SVs (in couple)
  - **Question:** which points to chose? → we focus on the boundary
  - We use a virtual multi-resolution grid

### Conclusion [Active learning]

- Allows one to limit the size of the training set size
  - but the approximation time is still exponential
  - produces a fast and compact controller

1. SVMs viability kernel approximation
2. Viability kernels active learning
3. Approximating capture basins with SVMs
4. Resilience computation
5. Conclusion - In practice

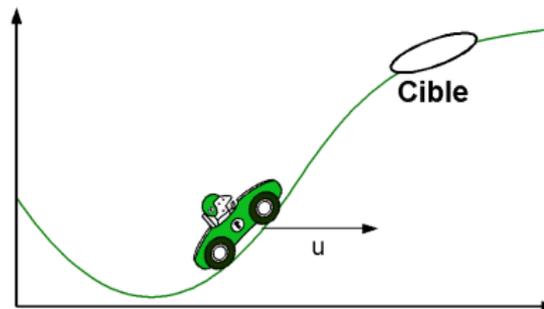

# Approximating capture basins with SVMs

A simple example: the car on the hill

- The car has to reach as fast as possible the top of the hill, while staying in a given state space
- Dynamical system

$$\begin{cases} p(t + dt) = p(t) + v(t)dt \\ v(t + dt) = v(t) + f(u(t))dt \end{cases} \quad (3)$$

- Under constraints
  - $p \in [p_{min}, p_{max}]$
  - $v \in [v_{min}, v_{max}]$
  - $u \in [-u_{max}, u_{max}]$

# Approximating capture basins with SVMs

## Définition

- **Capture basin at time  $t_{Max}$** : set of initial states that can reach the target before time  $\tau \leq t_{Max}$ , while staying in  $K$
- **Algorithm**: addition of one dimension, the time  $\tau' = -1$
- Approximation of the viability kernel of the extended system, with  $K \times [0, t_{Max}]$

$$\begin{aligned} \text{--if } x \notin C \quad F_C(x, \tau) &= \begin{cases} x'(t) = F(x(t), u(t)) \\ \tau'(t) = -1 \end{cases} \\ \text{--if } x \in C \quad F_C(x, \tau) &= 0 \end{aligned} \quad (4)$$

# Approximating capture basins with SVMs

## Algorithm

### Approximation algorithm in the initial state space

- Iterative algorithm, based on the viability kernel algorithm
- Initialization:  $+1$  if  $x \in C$ ,  $-1$  otherwise
- Learning set: points of the grid with label
  - $+1$  if there exists a control that will lead the point to the current target at the next time step
  - $-1$  otherwise

# Approximating capture basins with SVMs

## Algorithm

### Theorem [outer approximation]

Under some conditions on the learning quality and on the dynamics, the algorithm provides a capture basin approximation that converge towards the actual capture basin when the resolution of the grid tends to 0

### Theorem [inner approximation]

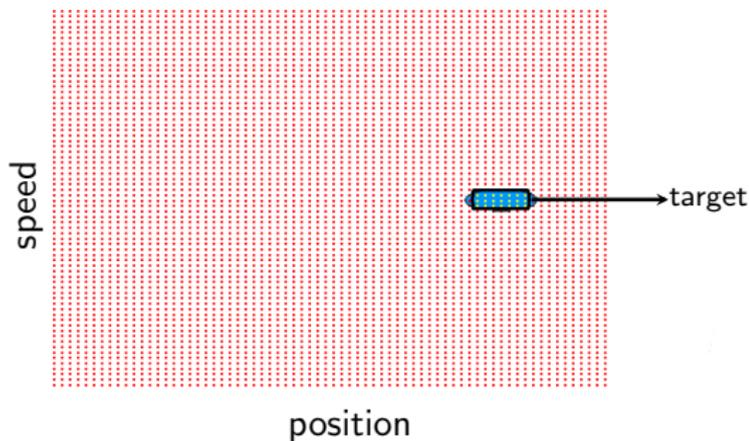

Under some conditions on the learning quality and on the dynamics, the algorithm provides a capture basin approximation that converge towards the actual capture basin when the resolution of the grid tends to 0

### Conclusion [Capture basin approximation]

- Two versions of the algorithm
  - **allows** one to define a controller that guarantee to reach the target
  - **allows** one to work in high dimensional control space
  - **doesn't allows** one to deal with high dimensional state space

1. SVMs viability kernel approximation
2. Viability kernels active learning
3. Approximating capture basins with SVMs
4. Resilience computation
5. Conclusion - In practice

# Resilience computation

## Extension of the capture basin algorithm

### Extension to resilience values computation

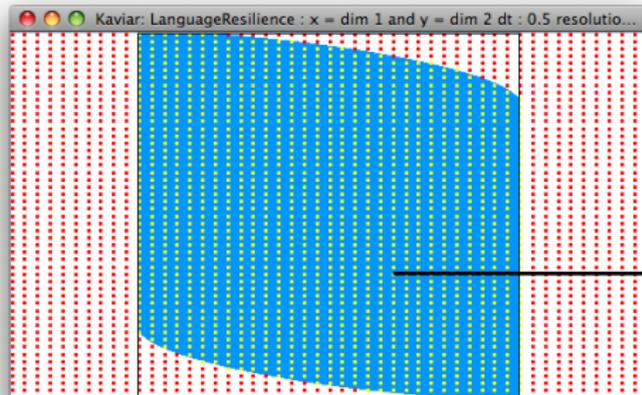

- Definition [Martin] : inverse of the restoration cost of the properties of interest lost after disturbances
- Property of interest: viability constraint set
- Under some conditions, we can use the capture basin approximation algorithm
  - target: viability kernel
  - set of states that can go back to the target with a cost  $c \leq c_{max}$

1. SVMs viability kernel approximation
2. Viability kernels active learning
3. Approximating capture basins with SVMs
4. Resilience computation
5. Conclusion - In practice

## How to obtain a good approximation?

- Know your system and dynamics! especially the speed of the dynamics, in order to define good time step, grid size, dt etc.
- Especially with the resilience computation

## How to know if I can rely on my approximation?

- Use the controller! Starting from several starting points, you can produce a trajectory that remains inside the kernel + leaves  $K$
