Table 6
Summary statistics for EU exposures to products

Consumer	Body lotion (g/day)	Deo/AP non-spray (g/day)	Deo/AP spray (mg/day)	1 stick (mg/day)	Facial moisturiser (mg/day)	Shampoo (mg/day)	Toothpaste (mg/day)
Mean	4.34	0.90	3.49	24.61	0.91	6.01	2.09
Median	4.36	0.82	3.15	17.11	0.85	5.50	2.39
P90	7.82	1.31	6.10	36.55	1.54	10.46	2.70
P95	9.05	1.81	7.20	72.51	1.80	12.18	2.95

Table 7
Summary statistics per kilogram body-weight for EU exposures to products

Consumer	Body lotion (mg/kg/day)	Deo/AP non-spray (mg/kg/day)	Deo/AP spray (mg/kg/day)	1 stick (mg/kg/day)	Facial moisturiser (mg/kg/day)	Shampoo (mg/kg/day)	Toothpaste (mg/kg/day)
Mean	47.87	12.85	49.97	0.39	13.62	85.99	29.85
Median	48.27	11.77	41.22	0.26	12.62	77.96	24.67
P90	123.23	22.08	87.79	0.90	24.14	150.49	41.29
P95	144.80	26.57	107.01	1.17	28.68	176.77	48.61

Fig. 4. EU 15 body lotion (g/day) consumers only (males and females).

We are therefore interested in the sensitivity of A to the changes in F and AP .

We followed a Monte Carlo approach with a regression analysis such as described in Helton (1993). Given the model of Eq. (3) and a data table obtained from repeated Monte Carlo evaluations of the model, the regression analysis attempts to fit the model output y to the linear model

$$A = \beta_1 F + \beta_2 AP + \beta_3 \quad (4)$$

Note that the β_i are dimensioned parameters. Eq. (4) can be expressed as

$$\frac{(A - \bar{A})}{s_A} = \beta_1 \frac{(F - \bar{F})}{s_F} + \beta_2 \frac{(AP - \bar{AP})}{s_{AP}} \quad (5)$$

where the β_i are referred to as Standardized Regression Coefficients (SRC), and they have the form

$$\beta_i = \frac{\bar{y}}{s_i} \quad (6)$$

Furthermore, \bar{y} is the sample mean of A , and similarly with F and AP . The symbol s refers to a standard deviation, so s_A is the sample standard deviation for A , and so on.

Given this representation, the coefficients β_1^2 and β_2^2 have an interpretation as the contributions to the overall variance of F and AP , respectively. Thus, the larger of the two values indicates that the associated parameter contributes most to the overall variance. This analysis assumes that there is no correlation between the input parameters, and that the variance may be decomposed into linear terms only – higher order variance terms are zero. Under these conditions, the relation

$$\beta_1^2 + \beta_2^2 = 1 \quad (7)$$

holds. Neither of these conditions has been found to hold in our case, but we assume that the model is within reasonable proximity to these conditions, and perform the analysis on this basis.

Concave:

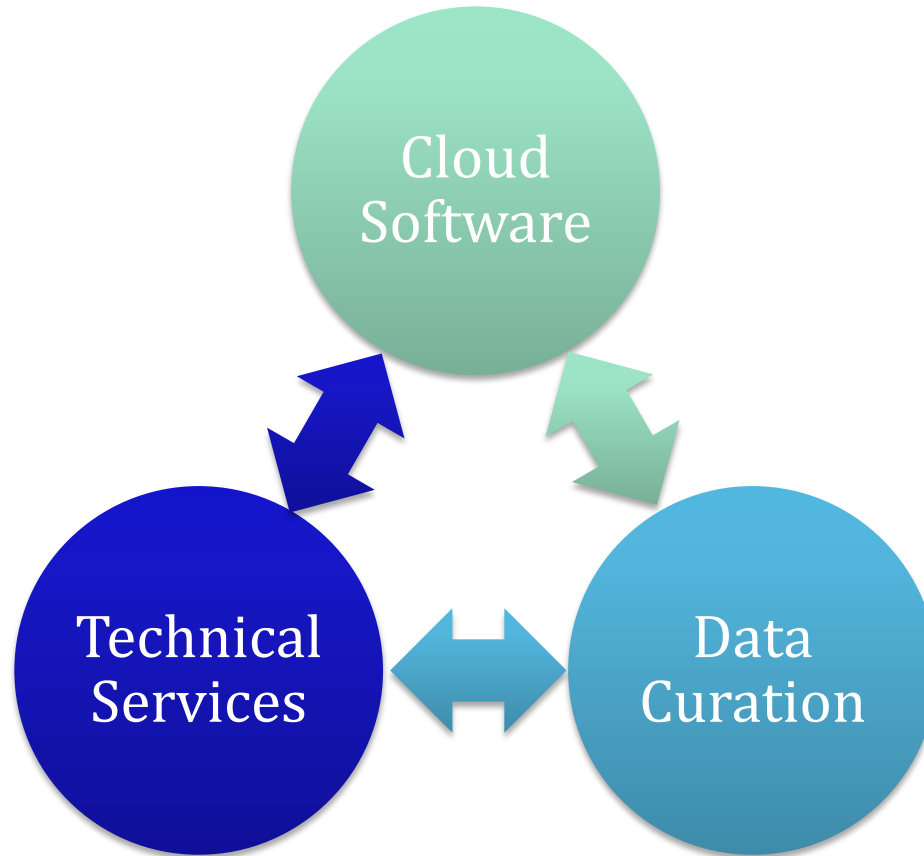

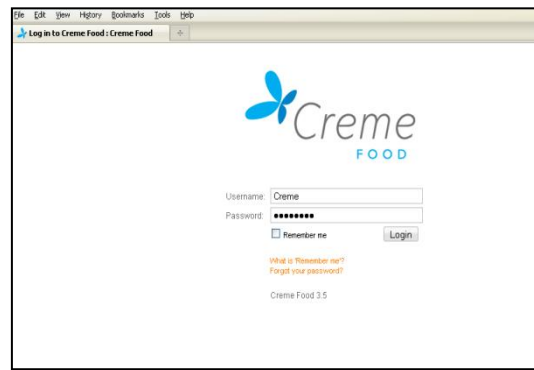

- The analysis described above assumes that the input parameters are not correlated. Clearly this is not the case for four products in this study. It is most notable in the case of isothepate – the SRC coefficients sum to more than one – this may be a case of reduction of overall variance due to correlation causing the ratio in Eq. (6) to be greater than one. In each of the products which exhibit correlation between the frequency of use and the amount used, the sum of the β terms is larger than the R^2 value might indicate, so similar effects may be manifesting.

Fig. 4. 50 (1) body mass (g/100g) response and (2) reduced viscosity.

We are therefore interested in the sensitivity of β to the change of μ and σ .

We consider a linear least squares with regression analysis to such an effect in DeWitt (1970). Given the model of Eq. (7), and a data table obtained from repeated measurements of the product, the regression analysis attempts to fit the model against μ in the linear model:

$$y = \beta_0 + \beta_1 \mu + \beta_2 \sigma + \epsilon \quad (8)$$

Note that the β_i are dimensionless parameters. Eq. (8) can be expressed as:

$$\frac{y - \beta_0}{\sigma} = \beta_1 \frac{\mu - \mu_0}{\sigma} + \beta_2 \frac{AP - AP_0}{AP_0} + \epsilon \quad (9)$$

where the β are defined as an Unstandardized Regression Coefficient (URC), and they have the form:

$$\beta_1 = \frac{\mu - \mu_0}{AP_0} \quad (10)$$

where μ_0 is the sample mean of μ , and AP_0 is the sample mean of AP . The symbol ϵ refers to a random deviation, so ϵ is the sample standard deviation that ϵ add to y .

Given this representation, the coefficients β_1 and β_2 have an interpretation as the contribution to the overall variance of y and AP , respectively. Thus, the larger of the two values indicates that the associated parameter was dominant in the overall variance. This analysis assumes that there is no correlation between the input parameters, and that the variance can be decomposed into linear terms only – higher order variance terms are zero. Under these conditions, the relative:

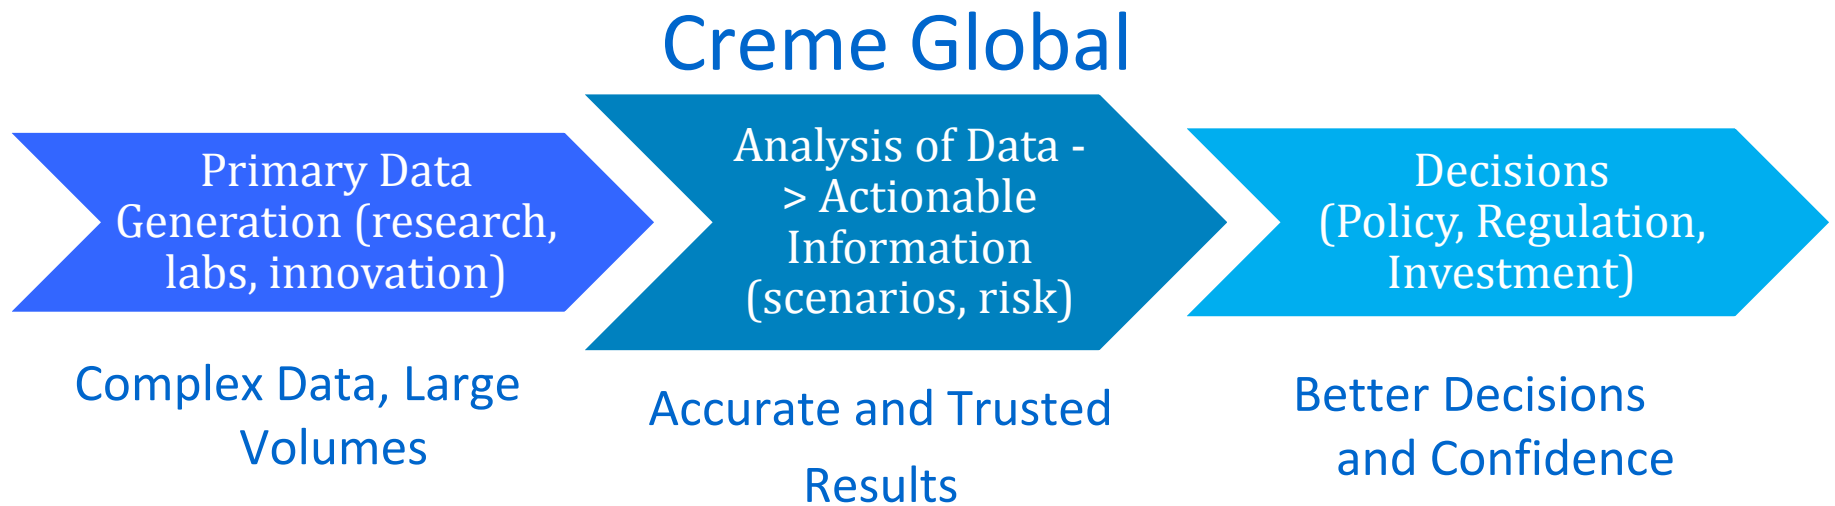

$$\beta_1^2 + \beta_2^2 = 1 \quad (11)$$

holds. Neither of these conditions has been found to hold in our case, but we assume that the result is within reasonable proximity to these conditions, and perform the analysis on this basis.

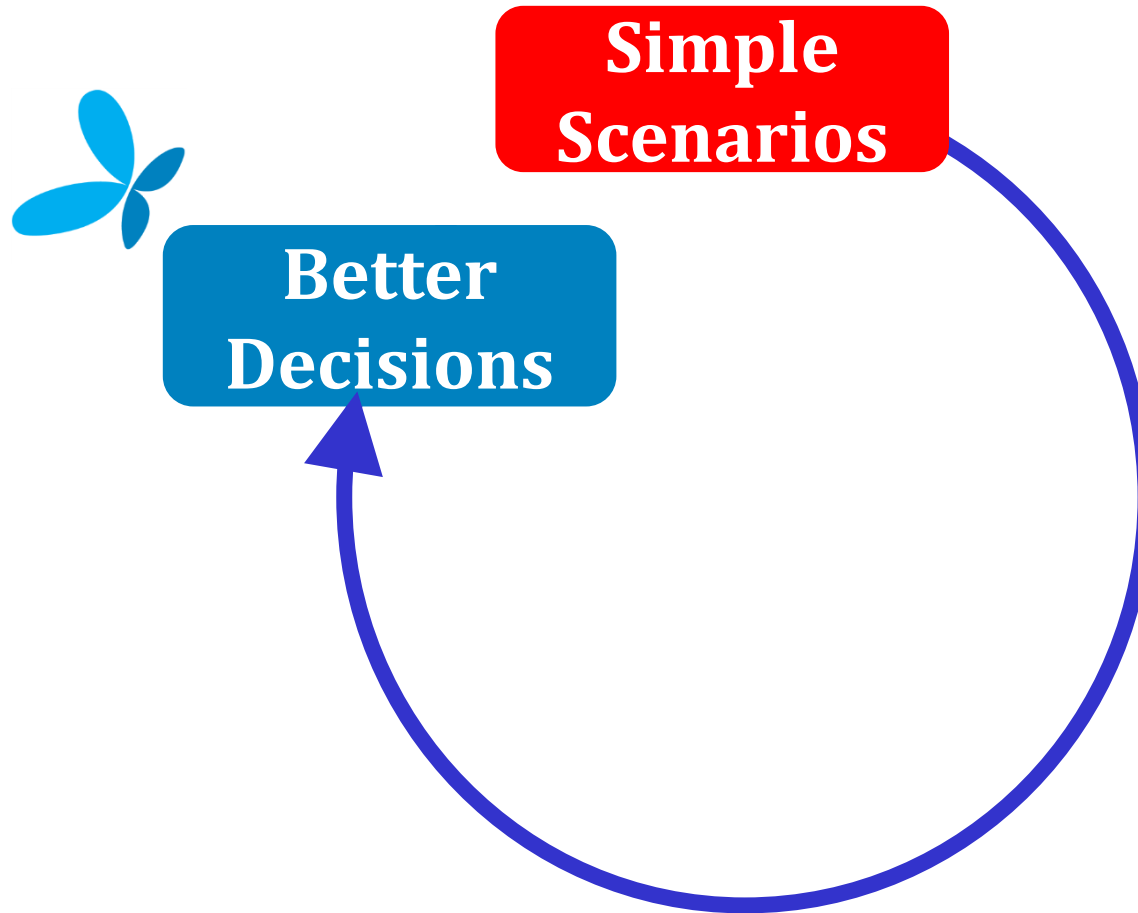

Given:

- The analysis described above assumes that the input parameters are uncorrelated. Clearly this is not the case for four products in this study. It is worth noting in the case of lactulose – the URC coefficients are so large that one – this may be a case of reduction of overall variance due to correlation causing the relation in Eq. (11) to be positive that one results in the previous which can be concluded because the frequency of use and the response that the use of β terms is larger than the β value might indicate, so similar effects may be considered.
